- Summary

The Project

The main mining operations of Canadian Royalties Inc. (CRI) for the Nunavik Nickel Project (NNiP) are located 20 km southeast of Katinniq, approximately 80 km west of Kangiqsujuaq, and 140 km southeast of Salluit. The NNiP was developed to exploit several sulphide ore deposits, including seven deposits: Expo, Méquillon, Ivakkak, Mesamax, Allammaq, Puimajuq, and Inukshuk.

Mining of the Allammaq deposit was completed in 2023, while mining of the Puimajuq deposit ended in 2022. As of March 2026, open-pit mining at the Expo, Ivakkak, and Méquillon deposits have transitioned from open-pit to underground mining operations, which remain ongoing. The Inukshuk deposit is expected to begin operations in 2027.

The development of the NNiP required the establishment of various infrastructures:

- Housing facilities for workers and camps
- A 16.6 MW generator fleet
- Garages, warehouses and workshops
- Accumulation and storage areas for waste rock, ore and tailings
- Roads and port facilities at Deception Bay
- Water reservoir created by the construction of a sill bridge
- Waste management facilities and other related facilities.
- Ore processing plant, located within the Expo industrial complex, for the production of nickel and copper concentrates

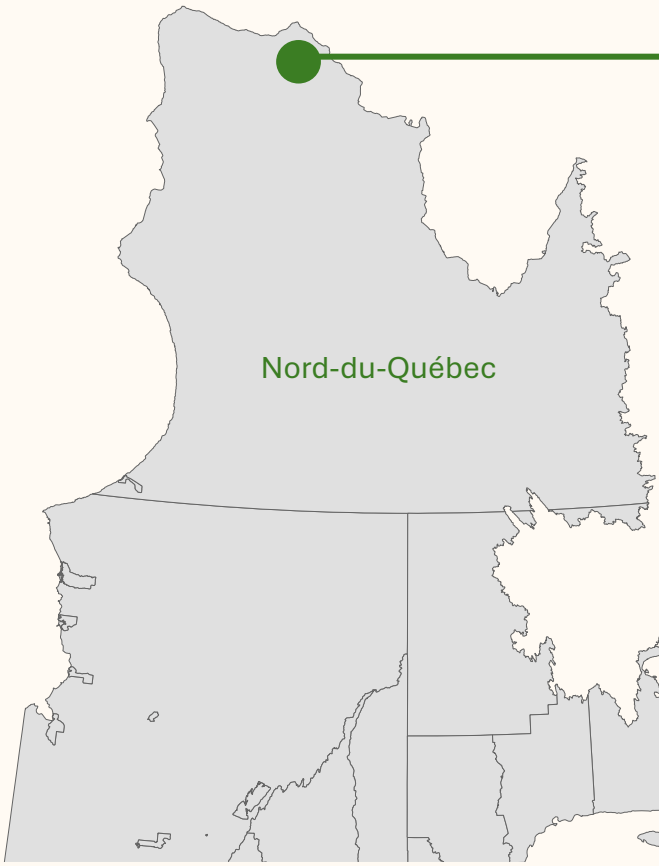

Ore from each deposit is transported to the Expo industrial complex, where it is placed on the ore stockpile and then transferred to the processing plant to produce copper and nickel concentrates. The concentrates are transported by covered truck-trailers to the port facilities at Deception Bay, from where they are shipped to smelters in Europe. Tailings generated by the concentration process are pumped and deposited into the tailings cells of the tailings management facility, which is also located at the Expo mining complex. This management facility will remain in operation until mining of the last NNP deposit has ceased.

The NNiP was the subject of an Impact and Benefit Agreement (Nunavik Nickel Agreement, also known as the IBA) with Inuit stakeholders in 2008.

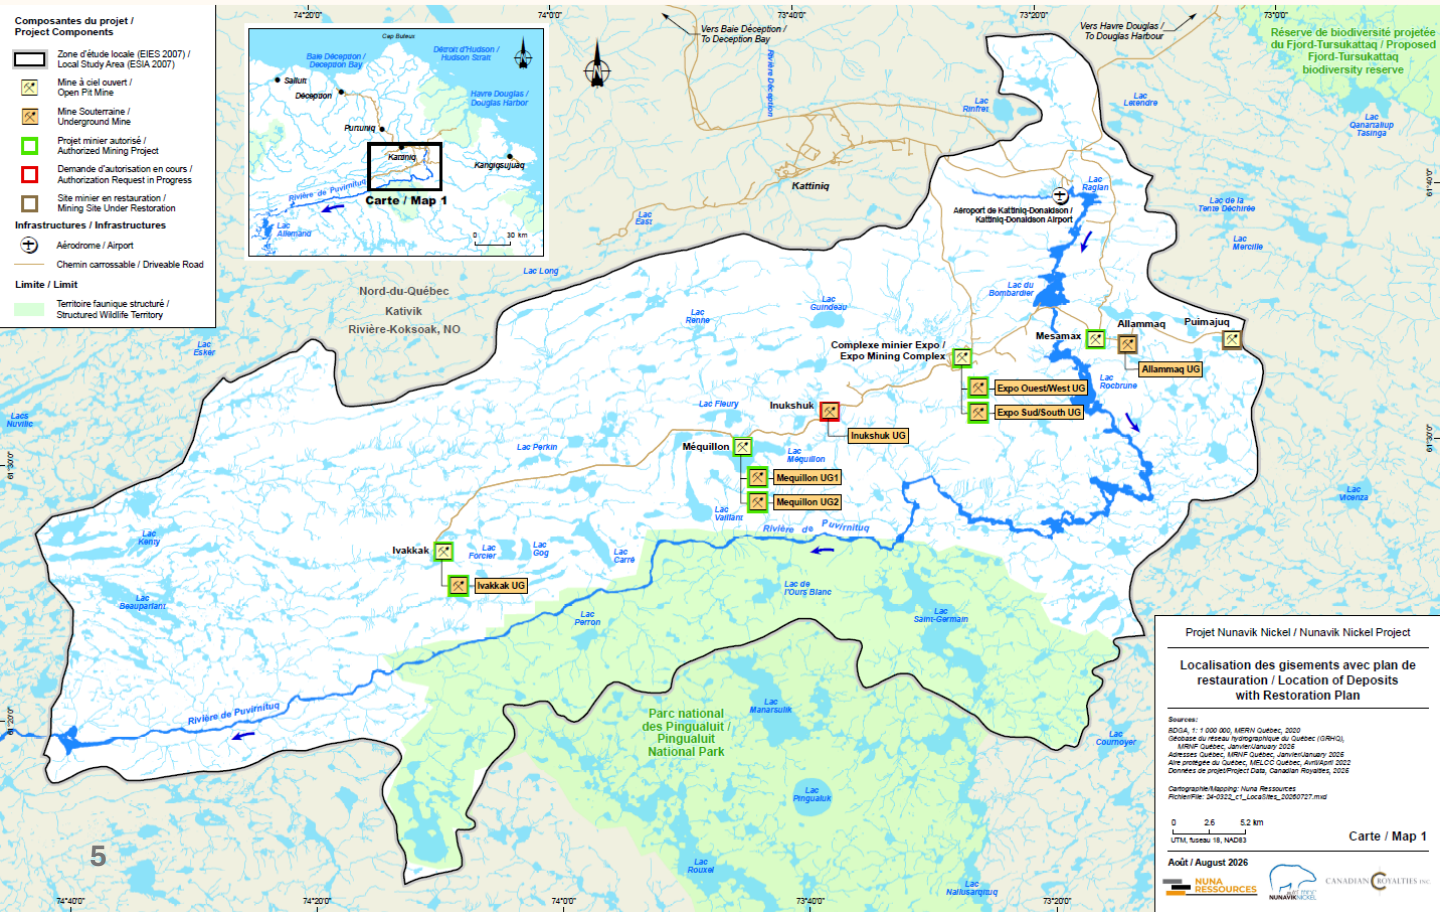

The Project

Nunavik Nickel (NNiP)

Key Definitions

Ore

Rock excavated during mining operations that contains useful minerals (such as metals) in sufficient quantities to have commercial value

Waste Rock

Rock excavated during mining operations that does not contain enough ore to be processed

Waste Rock Pile*

An outdoor storage area for storing excavated rock with no mining value

Ore Stockpile*

An outdoor storage area used to stockpile ore prior to processing

*Stockpiles may be temporary, meaning that waste rock and ore are transferred on an ongoing basis to their designated storage, processing, or disposal locations.

Mining Tailings

Waste material remaining after ore processing, that must be properly managed to prevent water contamination

Tailings Cells

An outdoor containment area within a tailings storage facility where mine tailings are deposited and stored

Main Collection Pond (MCP) and Lower Collection Pond (LCP)

An open-water structure designed to collect and manage runoff and drainage water

Dike

A structure designed to obstruct, contain, or control the flow of water

Spillway

A structure designed to divert or discharge water retained by a dike, dam, or containment structure when water levels exceed a specified threshold, such as the crest elevation of the dike

Esker

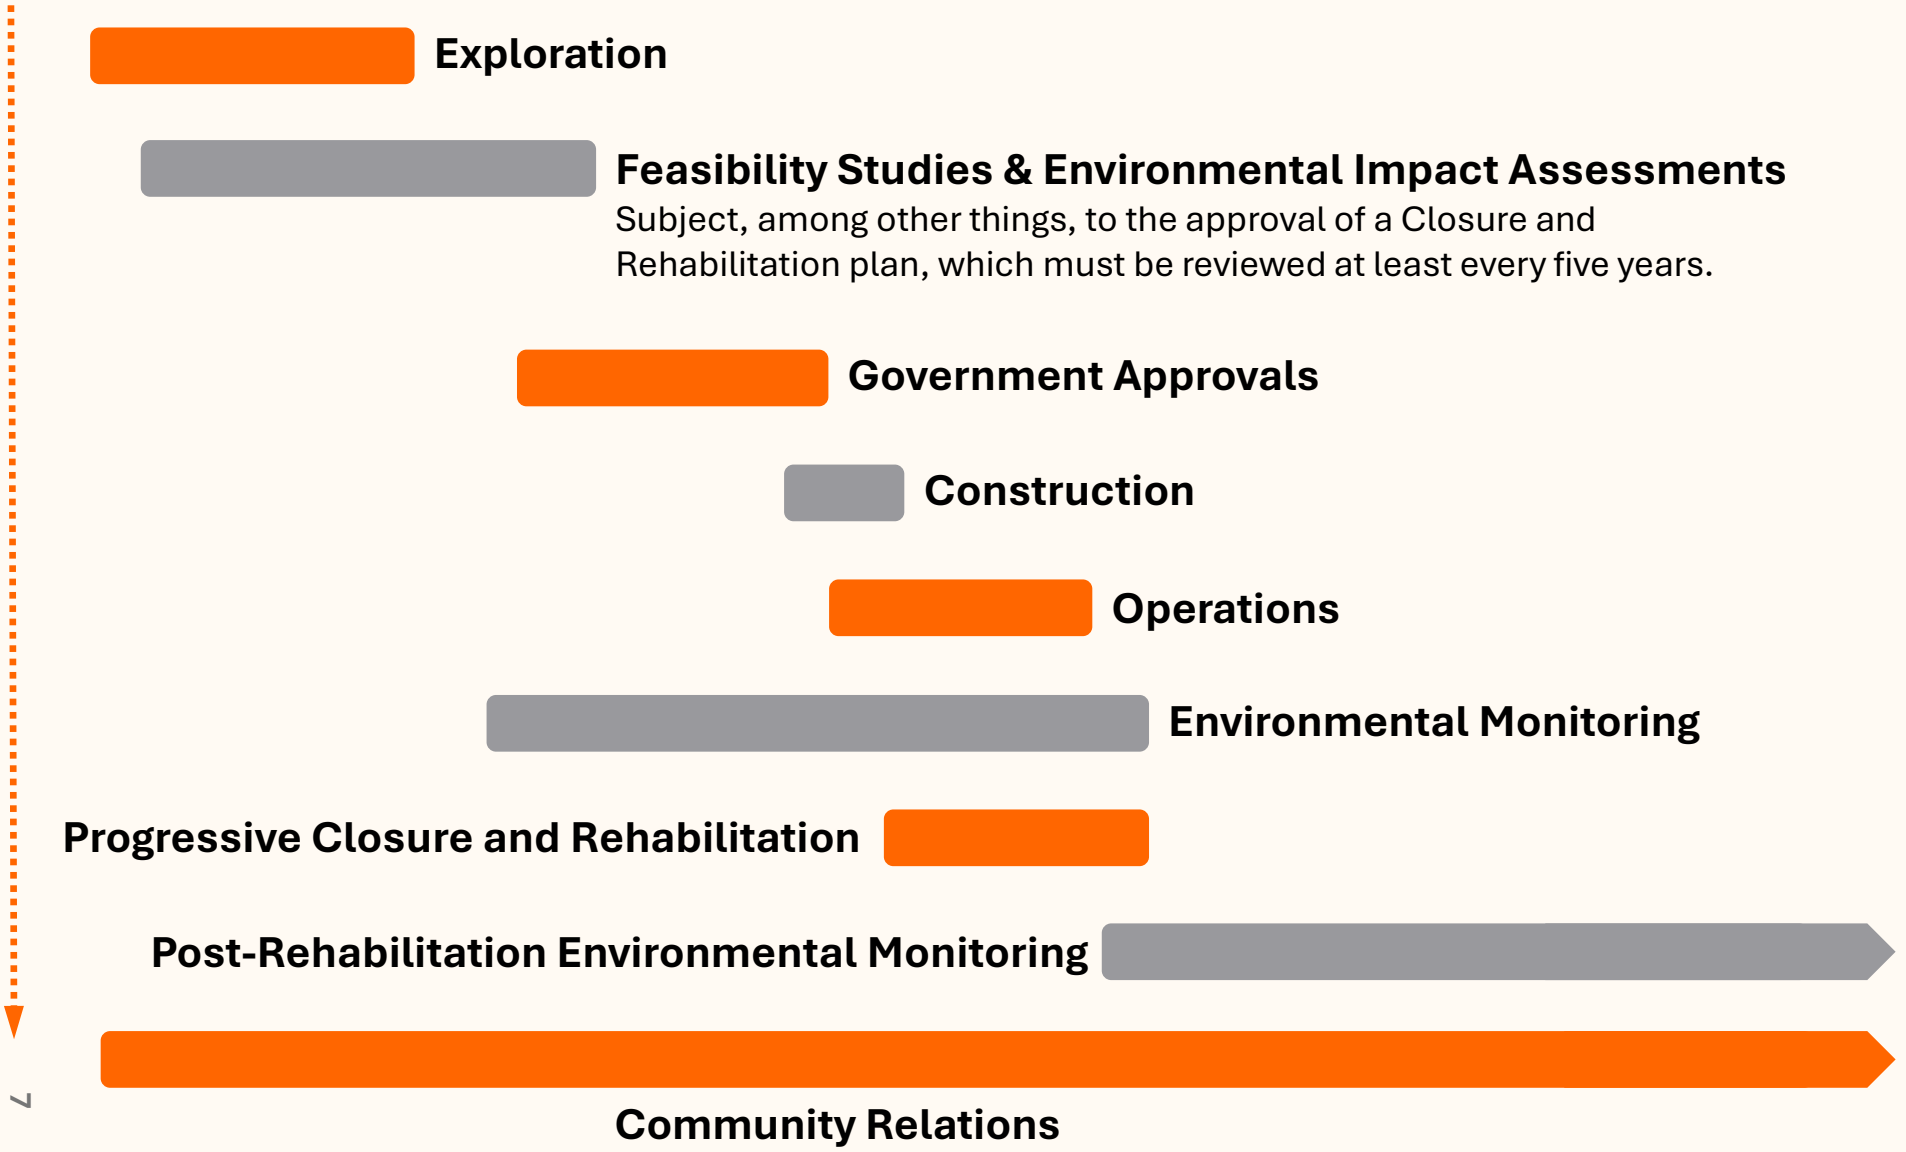

A long ridge of sand and gravel deposited by subglacial rivers during the retreat of glaciers

Potentially acid-generating (PAG) / Acid Mine Drainage (AMD)

In mining environments, water accumulates in collection ponds, pits, and drainage and diversion ditches. Certain types of sulphide-bearing rock or tailings can produce acidity when exposed to air and water. This characteristic is referred to as Potentially acid-generating (PGA).

When this potential is realized, it can result in acid mine drainage (AMD): An acidic water discharge that dissolves and transports metals, potentially contaminating soils and aquatic environments.

Key Stages of Our Mine Development

Ore Extraction and Processing

The 5 Stages

Exploration and Evaluation

Identification of a mineral deposit, assessment of its grade and size, and acquisition of mining rights

1

Mines Construction

Overburden removal for open-pit mines or shaft sinking for underground mines

2

Ore Extraction

Drilling blast holes in rock and blasting to extract ore

Loading and Hauling

Loading of broken ore to a permanent ore stockpile area (sometimes via temporary stockpile areas) located near the ore processing plant

3

Processing and Recovery

Crushing, grinding, and separation of valuable minerals from waste rock to produce a marketable concentrate

4

Mine Closure

Site rehabilitation to minimize environmental impacts

5

Mine Site Rehabilitation

The 4 Key Principles

The development of the entire NNiP was planned with the subsequent rehabilitation phase in mind, with the objective of restoring the land to a condition compatible with the surrounding environment. The work planned upon cessation of NNiP operations will ensure compliance with the following mine site rehabilitation requirements in Québec:

Ensure public safety and minimize health risks

Limit the generation and spread of contaminants into the natural environment

Restore the site to a condition that closely resembles the original ecosystem

Restore infrastructure to a condition compatible with future land use

As provided for under the Impact and Benefit Agreement (IBA), mine site rehabilitation must fully satisfy the requirements of both government authorities and Inuit communities, with the latter playing an active role in defining what constitutes a satisfactory outcome. The Agreement further provides that Inuit communities may require additional studies, beyond those mandated by government authorities, on matters such as contamination of fish or sediments resulting from current or past NNiP activities.

Financial Guarantee

The financial guarantee amount corresponds to the anticipated costs of carrying out all activities outlined in the rehabilitation plans for the various mine sites, as well as the associated environmental and geotechnical monitoring programs.

As of 2026, the financial guarantees provided to the Québec Ministry of Natural Resources and Forests (MNRF) for mine site rehabilitation total nearly $106.3 million.

Mine Site Rehabilitation

General NNiP Measures

Underground Mines and Pits

Underground Mines

- Underground mines will be backfilled with waste rock during operations, thereby reducing the risk of ground collapse.
- Access to the portals will be blocked by rock barricades, while openings such as emergency exits and ventilation raises will be sealed with concrete caps. Trilingual signs will be installed to restrict access.

Pits

The stability of pit walls will be assessed prior to flooding. The risk of wall failure will be reduced through controlled blasting of potentially unstable sections.

Rapid flooding of the pits will help limit the potential to generate for acid mine drainage. The pits will be secured using waste rock barriers and trilingual warning signs.

Accumulation Areas

Main Ore Stockpile at the Expo Site and Secondary Ore Stockpiles at the Satellite Sites

All ore remaining on the secondary stockpiles will be transported to the Expo site. The surface of the ore stockpiles will be scraped and removed until the soil meets the regulatory limits in force, particularly with respect to metals and hydrocarbons. The removed material will be processed at the ore processing plant or disposed of in an appropriate location, such as the potentially acid-generating waste rock pile at each site, prior to the installation of an impermeable cover. The ground surface will then be graded to control erosion and restore a natural appearance.

Non-PAG Waste Rock Piles

They will be regraded to limit wind erosion and ensure long-term stability.

PAG Waste Rock Piles

They will be reclaimed using a multilayer impermeable cover system consisting of a synthetic polyethylene liner and layers of non-PAG and inert material (sourced, for example, from an esker).

Temporary Waste Rock Piles

Managed in a manner similar to the ore stockpiles. Once the waste rock pile has been depleted, its surface will be scraped, and the recovered material will be returned to underground mines for backfilling or placed on a PAG waste rock pile at another site. The residual soil will be characterized to ensure compliance with the regulatory limits established under applicable regulations. The site will then be graded to control erosion and restore a natural appearance.

Water Management Infrastructures

Water management infrastructures will not be restored until satisfactory water quality has been demonstrated. Accordingly, these facilities will remain operational until such water quality objectives have been achieved.

Main Collection Pond (MCP) and Lower Collection Pond (LCP)

Contaminated sediments will be removed and transported to appropriate accumulation areas within the NNiP or, if no suitable site is available, to facilities in southern Québec. The ponds will be backfilled (where they were created through excavation) with non-PAG materials to promote runoff and prevent water accumulation. The dike will be removed or breached. Finally, the areas will be graded to restore natural drainage patterns.

Mine Site Rehabilitation

General NNiP Measures

Water Management Infrastructure (Continued)

Clean Water Ditches, Contact Water Ditches, and Berms

For contact water ditches, any contaminated sediments present will be managed in the same manner as those in the collection ponds. The ditches will be backfilled and graded to restore a natural appearance and re-establish natural drainage patterns. Berms (earthen embankments used to retain or delineate an area) will be leveled.

Water Treatment Plants (WTPs)

They will be dismantled once they are no longer required. No chemical reagents or waste materials (managed in accordance with the Waste Management Plan) will be left on site.

Buildings and Support Infrastructures

Buildings and Infrastructures

All buildings and infrastructures not required for post-closure monitoring will be dismantled. A particular emphasis will be placed on maximizing the recovery of non-ferrous metals and scrap metal for shipment to authorized recycling facilities in southern Québec.

Support Infrastructures (Pipelines and Storage Tanks)

They will be removed. Areas used for the storage or transportation of hazardous materials will be characterized and, if necessary, decontaminated.

Pile Foundations

Pile foundations will be cut off at ground level or removed wherever feasible. Other supporting materials will be removed, reused, or disposed of as scrap metal or at the NNiP northern landfill site (LEMN). The ground will be graded to restore the natural appearance of the site.

Wind Turbines

They will be dismantled and transported to Deception Bay.

Transport Infrastructures

Roads

Local communities and the MNRF will be consulted to determine their preferences regarding the removal or retention of roads. Only secondary access roads will be removed or scarified. Road embankments will be graded and stabilized by reducing slope angles, natural gravity drainage will be maintained, and access will be restricted through the construction of earth berms. All transportation infrastructure required for post-operation and post-rehabilitation monitoring, or by the MNRF, will be retained as needed.

Sill Bridge

It will be dismantled to restore Bombardier Lake to its original water level and to re-establish the natural habitat of the Puvirnituq River.

Deception Bay Infrastructures

CRI will offer to transfer ownership of the Deception Bay wharf to the local government. If no agreement can be reached, the wharf will be dismantled and transported to southern Québec by tugboat. All buildings, including the warehouse, camp facilities, and garage, will be dismantled.

Northern Landfill Site (LEMN)

The LEMN located at the Expo mining complex will be covered with inert esker material and protected against erosion. Fencing will be dismantled, and the metal will be recovered for recycling or disposed of within the site.

Mine Site Rehabilitation

General NNiP Measures

Camps

Upon cessation of NNiP mining operations, all remaining camps will be offered to local Nunavik communities. Should these communities decline the offer, all camps existing at the time of mine closure will be dismantled.

Equipment and Heavy Machinery

All surface equipment and heavy machinery will be sold, recovered, or sent to an authorized disposal facility. Recoverable materials and equipment will be set aside and donated or sold through salvage and second-hand markets.

If there is interest from local communities in these materials and equipment, CRI will encourage the creation of an organization similar to the Réseau des ressourceries to give these materials a second life through reuse and recovery initiatives.

Borrow Pits

Borrow pits used for construction purposes will be utilized for rehabilitation activities and will subsequently be closed, recontoured, and reclaimed to stabilize slopes and prevent ground instability and erosion.

Hazardous Materials

No hazardous materials will remain on the mine site following the cessation of mining operations. All hazardous and recyclable materials will be transported to appropriate facilities in southern Québec for disposal or recycling.

Contaminated Soils

A soil quality assessment will be conducted for all areas with potential contamination, and corrective measures will be implemented in accordance with applicable regulatory requirements.

Miscellaneous

Non-recoverable and non-recyclable waste materials will be disposed of in the LEMN.

Monitoring

Monitoring programs will be maintained until government authorities and local communities are satisfied with the rehabilitation outcomes.

Monitoring of Structural Integrity

Monitoring of the stability of structures left in place will be conducted for a minimum period of five to ten years following the cessation of mining operations, depending on the site. This monitoring is intended to confirm long-term stability, prevent potential sources of contamination, minimize erosion of restored surfaces, and enable the implementation of corrective measures where necessary.

Environmental Monitoring

Environmental monitoring consists of characterizing and monitoring surface water flowing through mine activity areas, particularly to assess the occurrence of acidification, as well as evaluating soil quality and the long-term stability of permafrost following mine closure and rehabilitation.

Environmental monitoring is carried out during both the post-operation and post-rehabilitation periods, the latter lasting at least five years and most often a minimum of ten years. Once water quality monitoring demonstrates that applicable criteria have been met, rehabilitation of certain infrastructures may proceed (ditches, MCP, WTPs, etc.). No revegetation activities are currently planned. Experimental trials in Nunavik will be conducted over the coming years in partnership with the Kativik Regional Government (KRG) and Laval University. The research program is currently being developed.

Expo Site

Exploitation
ongoing and continuing until mining activities have ceased at all deposits

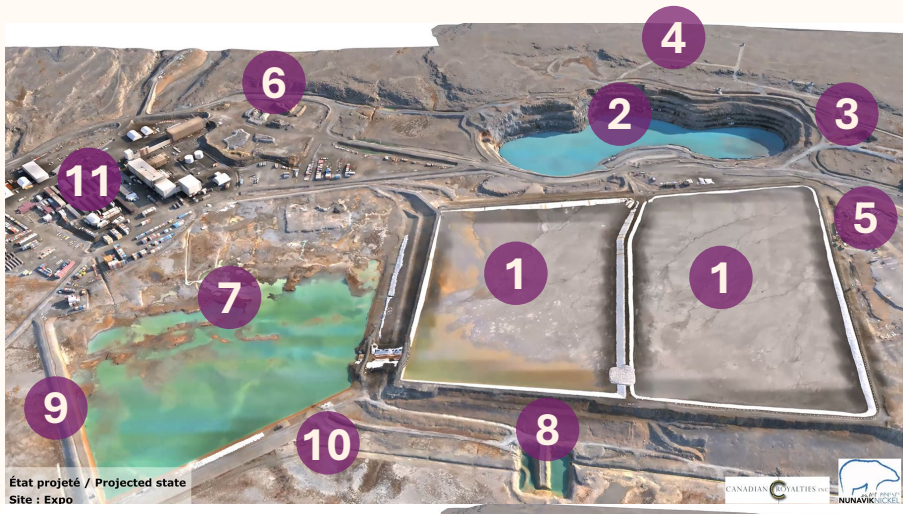

Monitoring
conducted until at least 2052 (Expo Complex and Deception Bay facilities)

Infrastructures

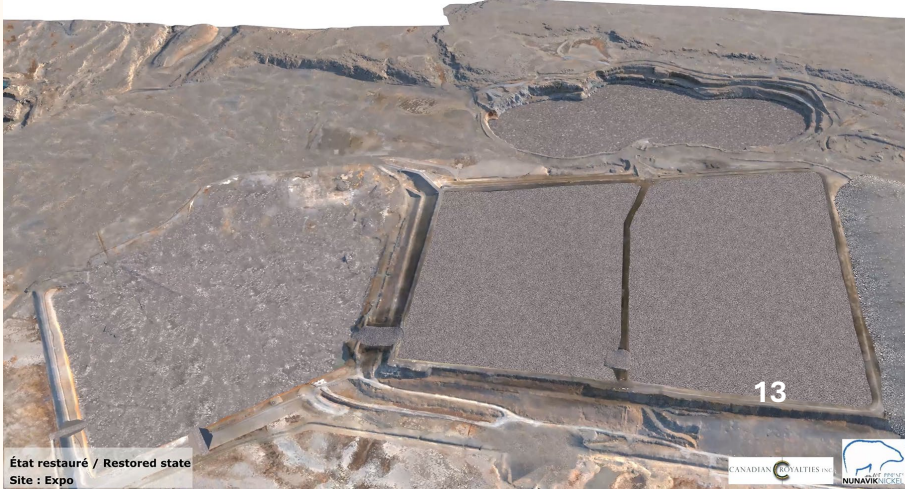

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the specific measures presented on the following page)

- Tailings Cells 1 and 2 **(1)** including dikes
- An open pit mine, the Expo pit, which is no longer in operation and now serves as tailings cell 3 **(2)**
- West underground mines (mining completed) **(3)** and south **(4)**
- PGA waste rock pile **(5)**
- Ore stockpile (receives ore from all NNiP deposits) **(6)**
- MCP **(7)**, LCP **(8)**, dike **(9)** and spillway **(10)**
- Pipelines: Fresh water, sanitary sewer, influent to the WTP, and effluent to the environmental discharge point
- Expo industrial complex **(11)**: Ore processing plant (or concentrator), WTP, wastewater treatment plant, garage, accommodation complex, warehouses, storage domes, two office platforms, power generators, various storage tanks, and material storage containers.

Current site (2025)

Projected Reclaimed Site

Expo Site

Specific Measures

Tailings Management Facility (Tailings Cells 1 and 2)

Rapid placement of a multilayer impermeable cover over tailings cells 1 and 2 following removal of excess water. The cover system will consist of a polyethylene geomembrane and layers of non-PAG inert material (e.g., esker-derived material) (2032-2037). A surface drainage system will also be installed on top of the closure cover to convey runoff and prevent water accumulation.

There is a potential for self-heating (spontaneous combustion of tailings), and preventive measures will be implemented, including lime addition, rapid progressive covering by sections, and the establishment of alert thresholds to identify potential hot spots.

Expo Pit (Tailings Cell 3)

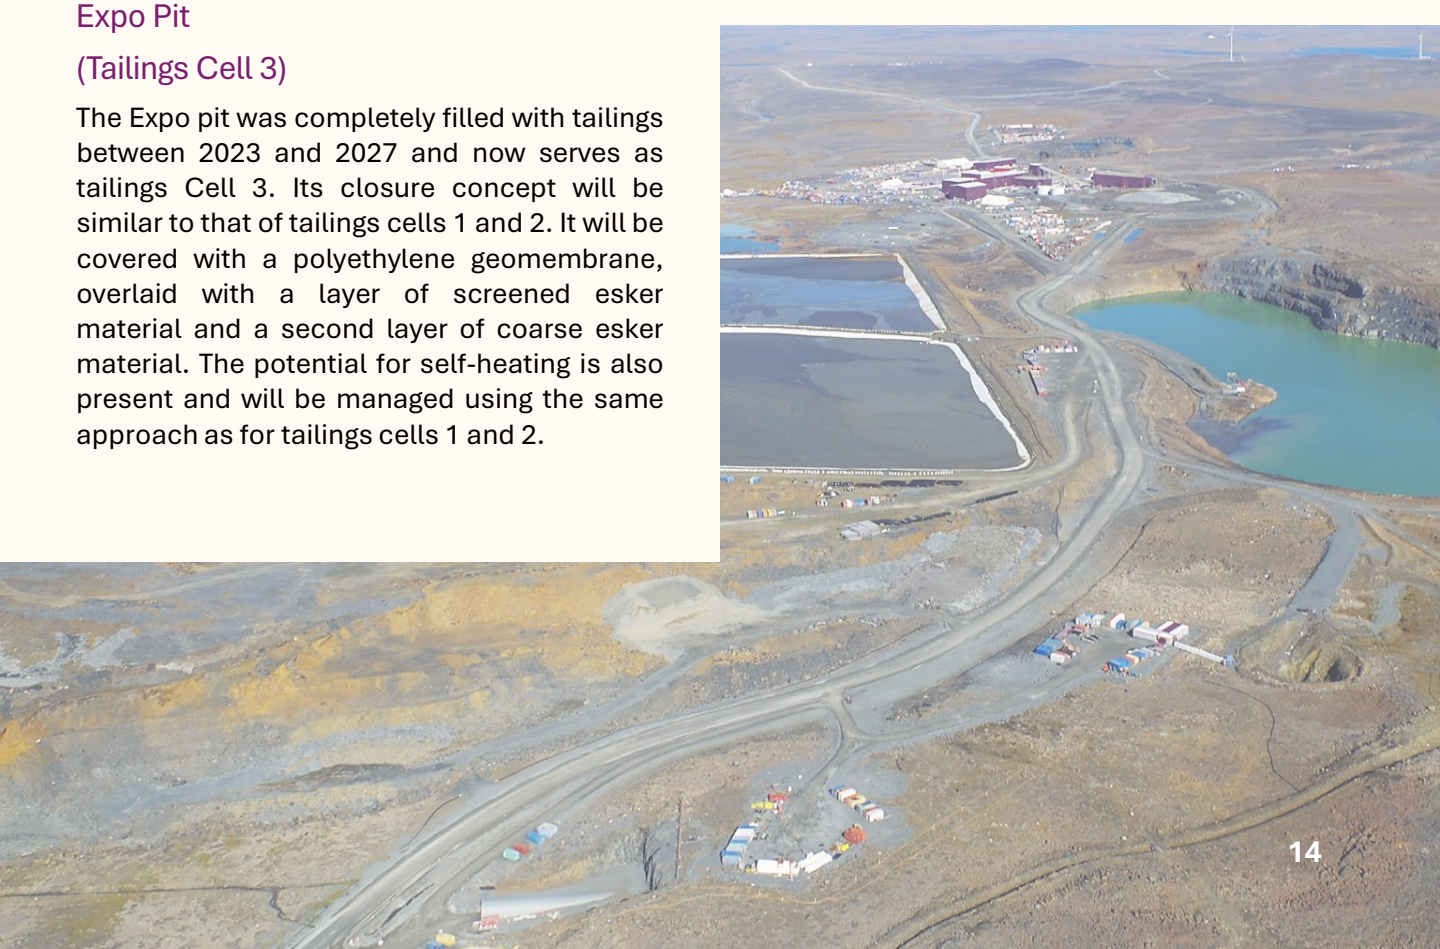

The Expo pit was completely filled with tailings between 2023 and 2027 and now serves as tailings Cell 3. Its closure concept will be similar to that of tailings cells 1 and 2. It will be covered with a polyethylene geomembrane, overlaid with a layer of screened esker material and a second layer of coarse esker material. The potential for self-heating is also present and will be managed using the same approach as for tailings cells 1 and 2.

Underground Mines

In addition to the general rehabilitation measures, further studies are underway to assess whether flooding of underground waste rock workings for oxidation control purposes is a feasible option for this site. If deemed feasible, the proposed measure will be submitted to the MNRF for approval.

MCP

In addition to the general rehabilitation measures, the northern contaminated portion of the pond dike will be removed, and the management approach for this material is yet to be determined. The dike itself will remain in place; however, breaches will be created in the structure to promote runoff and prevent water accumulation.

Méquillon Site

Exploitation
ongoing and end planned in 2029

Monitoring
conducted at least until 2046

Infrastructures

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Open pit **(1)**
- Underground mines 1 and 2 (with a shared access portal) **(2)**
- PGA waste rock pile **(3)**
- Temporary ore stockpile **(4)**
- MCP **(5),** dike **(6)** and spillway **(7)**
- Effluent discharge pipeline
- Buildings **(8)** : a site platform including a WTP, a warehouse, a garage, mobile trailers, storage containers, and associated support facilities.

Specific Measures

Pit

Natural flooding of the pit (through precipitation) is expected to take approximately 80 years. This process could be accelerated by pumping water from the MCP into the pit, provided that the water meets the criteria required to ensure that pit overflow water quality remains compliant with regulatory authorizations.

Underground Mines

In addition to the general rehabilitation measures, further studies are underway to assess whether flooding of underground waste rock workings for oxidation control purposes is a feasible option for this site. If deemed feasible, the proposed measure will be submitted to the MNRF for approval.

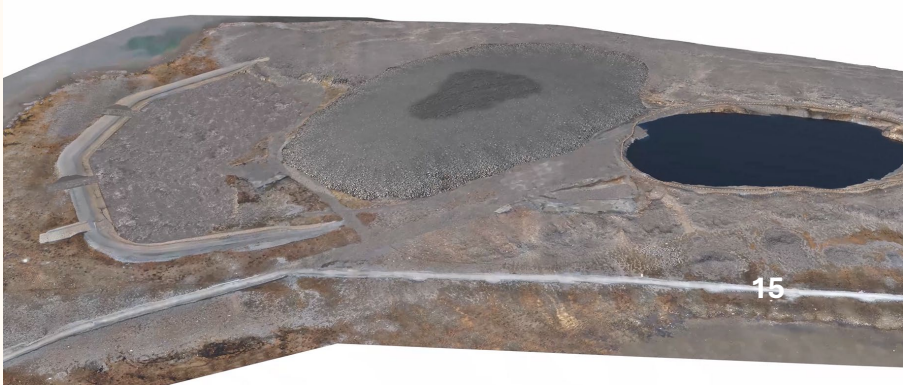

MCP

In addition to the general rehabilitation measures, the dike will remain in place; however, breaches will be created to promote runoff and prevent water accumulation. The spillway will remain in place.

Current site (2025)

Projected Reclaimed Site

Ivakkak Site

Exploitation
ongoing and end planned in 2031

Monitoring
conducted at least until 2048

Infrastructures

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Open pit **(1)**
- Underground mine (the portal is located within the pit) **(1)**
- PAG waste rock pile **(2)** and non-PAG **(3)**
- Temporary ore stockpile **(4)**
- MCP **(5),** LCP **(6),** dike **(7)** and spillway **(8)**
- Eflluent discharge pipeline
- Buildings : WTP **(9)**, infrastructure platform (mobile trailers, office, storage containers, generators, etc.) **(located to the North)**

Specific Measures

Pit

Complete flooding is expected to take approximately 12 years following the end of underground mining operations. Flooding may be accelerated using water from the site's WTP. An overflow structure will be constructed to allow excess water to flow into the MCP.

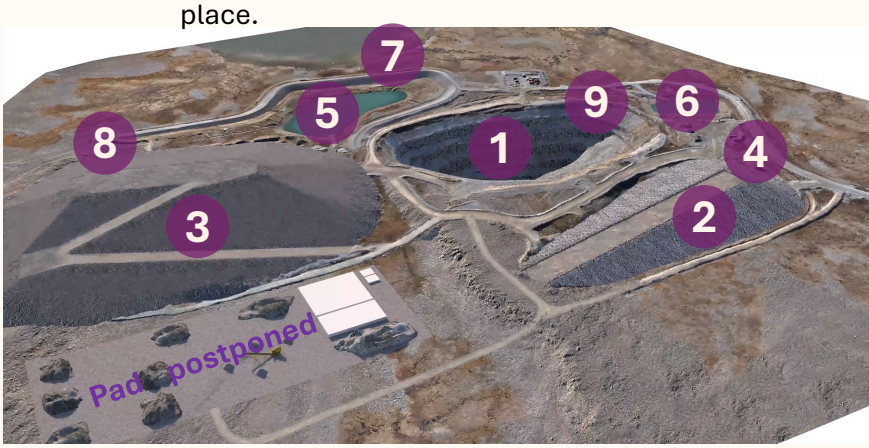

Underground Mine

In addition to the general rehabilitation measures, further studies are underway to assess whether flooding of underground waste rock workings for oxidation control purposes is a feasible option for this site. If deemed feasible, the proposed measure will be submitted to the MNRF for approval.

MCP

In addition to the general rehabilitation measures, the dike will remain in place; however, breaches will be created to promote runoff and prevent water accumulation. The spillway will remain in place.

Current Site (2025)

Projected Reclaimed Site

Mesamax Site

Exploitation
suspended, restart and end planned in 2030

Monitoring
conducted at least until 2046

Infrastructures

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Open pit **(1)**
- PGA waste rock pile **(2)**
- Temporary ore stockpile **(3)**
- MCP **(4)**, dike **(5)** and spillway **(6)**
- Effluent discharge pipeline
- Buildings **(7)** : A site platform including a garage, storage containers, and a WTP **(8)**

Specific Measures

Pit

Complete flooding of the pit is expected to take approximately 13 years following the end of mining operations. Pit dewatering (the removal of accumulated water) will cease once mining operations are completed. Pit flooding will be accelerated by pumping water from the MCP and by constructing peripheral drainage ditches. Once the open pit is filled, an overflow outlet will allow water to discharge and flow back to the MCP.

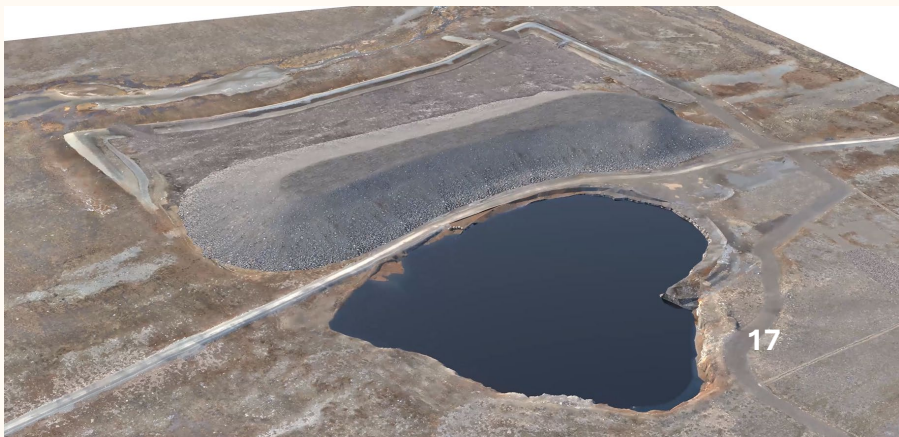

MCP

In addition to the general rehabilitation measures, the dike will remain in place; however, breaches will be created to promote runoff and prevent water accumulation. The spillway will remain in place.

Current Site (2025)

Projected Reclaimed Site

Site Allammaq

Exploitation
completed in 2023 and rehabilitation activities are ongoing

Monitoring
conducted at least until 2032

Infrastructures

(rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Underground mine **(1)**
- Temporary waste rock pile **(2)**
- Temporary ore stockpile **(3)**
- MCP **(4)** and dike **(5)**
- Pipeline conveying water from the (MCP) to the (MCP) at the Mesamax site
- Buildings or other structures **(6)** : Generator fleet, service building, mechanical workshop, warehouse, and other ancillary facilities.

Specific Measures

Underground Mine

All underground mine workings have been backfilled using waste rock from the Allammaq and Mesamax sites. Flooding of the underground workings is expected to occur over a period of 2 to 4 years (~ 717,500 m^3).

MCP

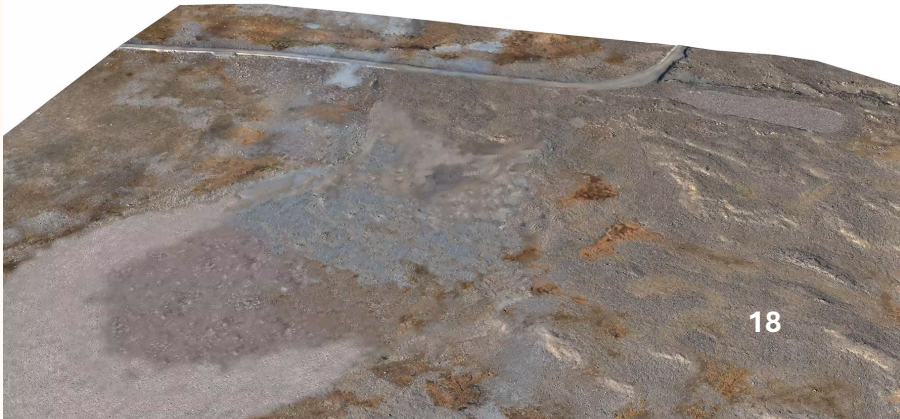

In addition to the general rehabilitation measures, the remaining water will be drained by completely dismantling the dike. Granular materials from the dike (gravel and sand) will be spread across the entire area formerly occupied by the surface infrastructure. The polyethylene liner that was incorporated into the dike, along with the discharge pipelines, will be removed and disposed of in the LEMN.

Already Completed

- Waste rock and ore removed (2023-2024)
- Buildings and infrastructure were largely relocated to the Expo site in 2025; however, rehabilitation work has not yet been fully completed.
- Underground workings backfilled with waste rock from the Allammaq and Mesamax sites.
- Complete backfilling of the underground mine portal.

Site before rehabilitation (2022)

Projected Reclaimed Site

Puimajuq Site

Exploitation
completed in 2022 and rehabilitation activities are ongoing

Monitoring
conducted at least until 2038

Infrastructures

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Open pit **(1)**
- Waste rock pile with two sections: PAG and non-PAG **(2)**
- Temporary ore stockpile area **(3)**
- MCP **(4),** dike **(5)** and spillway **(6)**
- Pipeline conveying water from the MCP to the MCP at the Mesamax site
- Buildings: An infrastructure platform containing mobile trailers, generators, and storage tanks **(located to the West)**

Specific Measures

PGA Waste Rock Pile
In addition to the general rehabilitation measures, all this material, together with the foundation of this section, will be placed in the Puimajuq open pit or transported to the Mesamax PAG waste rock pile (an alternative currently under evaluation).

Open Pit
The pit will be filled with waste rock and overburden, which will then be covered with a layer of inert waste rock. The pit will subsequently be flooded over a period of approximately five years using water from the Allammaq and Puimajuq MCPs or effluent from the WTP. Should all PAG waste rock be transported to the Mesamax waste rock pile, the pit would instead be allowed to flood naturally through precipitation.

MCP
In addition to the general rehabilitation measures, breaches will be created in the dike to allow water to drain into the natural environment. Because the MCP was created through excavation, it will be backfilled with non-PAG material.

Already Completed
Site secured and buildings dismantled (2023).

Current Site (2025)

Projected Reclaimed Site

Inukshuk Site

Exploitation
Planned from 2027 to 2036

Monitoring
conducted at least until 2041

Planned Infrastructures

(Rehabilitated in accordance with the general measures described on pages 9 to 11, in addition to the site-specific measures)

- Underground mine **(1)**
- Temporary waste rock pile **(2)**
- Temporary ore stockpile **(3)**
- MCP **(4)**
- Pipeline conveying water from MCP to the MCP at the Expo site
- Buildings **(5)** : Garage, offices, storage facilities, electrical room and generator platform, and associated infrastructure.

Specific Measures

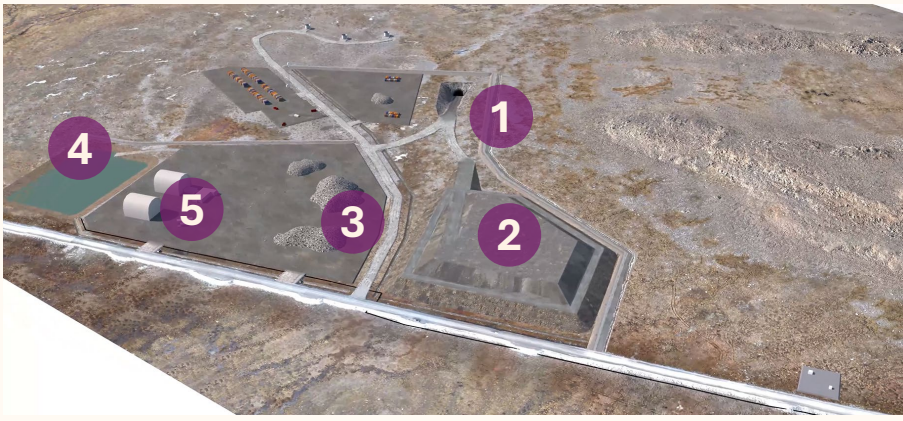

Underground Mine

It will be backfilled with all waste rock from the site, as well as a portion of the waste rock from the Expo and Méquillon sites, together with cemented rockfill (a mixture of waste rock and cement slurry placed underground). Additional studies are underway to assess whether flooding of underground waste rock workings for oxidation control purposes is a feasible option for this site. If deemed feasible, the proposed measure will be submitted to the MNRF for approval.

MCP

Its excavation will be backfilled with approved inert material and then graded to promote natural drainage. Prior to backfilling, soils and sediments will be characterized, and any potentially contaminated material will be removed and disposed of in the active tailings cell at the Expo site. The pump and pipeline will be dismantled. The site will be restored to its original condition.

Projected Final Site

Projected Reclaimed Site

OP: Open pit exploitation
UG: Underground exploitation

Summary

What Happens to All Infrastructures?

→ Before any rehabilitation activities are undertaken, **potentially contaminated materials** are removed and managed accordingly (for example, by being transported to appropriate accumulation areas or processed at the ore processing plant).

→ All **excavated features (such as ditches and ponds) and the LEMN** are backfilled or covered with inert or non-PAG material. All excavations, fills, dikes, berms, borrow pits, and disturbed surfaces are regraded to restore a natural appearance and/or natural drainage patterns while minimizing erosion.

→ Specifically for **open pits**, rapid flooding is carried out to limit oxidation and PGA, whereas **underground mines** are backfilled with waste rock and may subsequently be flooded. **Tailings cells and PAG waste rock piles** are restored using a multilayer low-permeability cover system incorporating a polyethylene geomembrane and layers of inert, non-PAG material.

→ **All buildings, camps, plants, the sill bridge, heavy machinery, and equipment (including power lines, pipelines, storage tanks, and other infrastructure)** will be dismantled, removed, recycled, or sold. Certain infrastructure, such as **the camps and the Deception Bay wharf**, will be offered or transferred to local communities. Other infrastructure, including **roads**, may be retained following consultation with local communities and the MNRF.

→ All **recyclable materials** will be set aside and either donated or sold for reuse. **Residual materials that cannot be recovered or recycled** will be disposed of in the LEMN.

→ No **chemical reagents or hazardous materials** will remain on site.

Water and Soil Protection

→ Each site is subject to water quality monitoring, including runoff water, before, during, and after rehabilitation activities for a minimum period of five years.

→ No contaminated water is discharged into the environment without first being treated by WTPs.

→ Potentially contaminated soils are assessed, and any necessary corrective measures are implemented in accordance with applicable regulatory requirements.

Environmental monitoring activities are carried out until the requirements of the MNRF, MELCCFP and local communities have been fully satisfied.

Will Nature Be Able to Recover?

→ No revegetation program is currently planned due to the unique northern environmental conditions. Experimental trials are being developed in partnership with the KRG and Université Laval to explore revegetation opportunities in Nunavik.

→ At some sites that have already been reclaimed, vegetation has gradually re-established itself over time.
